“The breaking of a wave cannot explain the whole sea.”
-Vladimir Nabokov
Objectives for Chapter 17

(a) Describe the properties of a wave, e.g., longitudinal or transverse, wavefronts, speed, wavelength, wave number, frequency and period.

(b) Apply the displacement function $s(x, t)$ to describe a traveling wave and relate this to pressure variation.

(c) Using the concept of phase difference, describe the production of interference.

(d) Relate the concepts of power, surface area, intensity, sound level and the displacement amplitude.

(e) Apply the concepts of standing waves and interference to describe musical instruments and beats.

(f) Calculate and describe the measured frequency of a wave when the source or detector are in motion; for motion exceeding the speed of sound, describe the shock wave and Mach cone angle.
A physics professor breathes in a small amount of helium and begins to talk. The result is that the professor’s normally low, baritone voice sounds quite high pitched. Why did this occur?
Sound waves are longitudinal waves that travel through solids and fluids.
**Sounds Waves**

*Sound waves are longitudinal waves that travel through solids and fluids.*

The source is at S and the wave propagates outward in a sphere. The pink lines are *wavefronts*. 
A wavefront is a surface over which the oscillations have the same value (density, in the case of sound).
A wavefront is a surface over which the oscillations have the same value (density, in the case of sound).

The direction of propagation is perpendicular to the wavefront.
The speed of a sound wave in a given material depends on that material’s density $\rho$ and its bulk modulus $B$.

$$v = \sqrt{\frac{B}{\rho}} \quad (1)$$
Sounds Waves

The speed of a sound wave in a given material depends on that material’s density $\rho$ and its bulk modulus $B$.

$$v = \sqrt{\frac{B}{\rho}} \quad (1)$$

A formal derivation of the wave velocity involves the use of $F_{\text{net}} = ma$ on an element of gas and the definition of $B = -\Delta p / (\Delta V / V)$.

A sound wave is a compression wave where the molecules oscillate back and forth around an equilibrium, like a spring.
A sound wave is a compression wave where the molecules oscillate back and forth around an equilibrium, like a spring.

- the distance between two high pressure points is the wavelength
- the molecules don’t travel very far
Sounds Waves

The particles in a sound wave behave like a traveling wave, described by the usual equation:

\[ s(x, t) = s_m \cos(kx - \omega t) \]
The particles in a sound wave behave like a traveling wave, described by the usual equation:

\[ s(x, t) = s_m \cos(kx - \omega t) \]

- wavenumber \( k = \frac{2\pi}{\lambda} \)
- angular frequency \( \omega = 2\pi f \)
- displacement amplitude \( s_m \)
Sounds Waves

But how does the pressure change? To connect position of particles to pressure, let’s use the bulk modulus:

\[ \Delta p = -B \frac{\Delta V}{V} \]
But how does the pressure change? To connect position of particles to pressure, let’s use the bulk modulus:

\[
\Delta p = -B \frac{\Delta V}{V}
\]

\[
V = A \Delta x
\]
But how does the pressure change? To connect position of particles to pressure, let’s use the bulk modulus:

\[
\Delta p = -B \frac{\Delta V}{V}
\]

\[
V = A \Delta x
\]

\[
\Delta V = A \Delta s
\]
Sounds Waves

But how does the pressure change? To connect position of particles to pressure, let’s use the bulk modulus:

\[
\Delta p = -B \frac{\Delta V}{V} \\
V = A \Delta x \\
\Delta V = A \Delta s \\
\Delta p = -B \frac{A \Delta s}{A \Delta x} \approx -B \frac{\partial s}{\partial x}
\]
But how does the pressure change? To connect position of particles to pressure, let’s use the bulk modulus:

\[
\Delta p = -B \frac{\Delta V}{V} \\
V = A \Delta x \\
\Delta V = A \Delta s \\
\Delta p = -B \frac{A \Delta s}{A \Delta x} \approx -B \frac{\partial s}{\partial x}
\]

Taking a derivative of \( s(x, t) \) w.r.t. \( x \), we find:

\[
\Delta p = Bks_m \sin(kx - \omega t) = v^2 \rho ks_m \sin(kx - \omega t) \quad (2)
\]
But how does the pressure change? To connect position of particles to pressure, let’s use the bulk modulus:

\[
\Delta p = -B \frac{\Delta V}{V}
\]

\[
V = A \Delta x
\]

\[
\Delta V = A \Delta s
\]

\[
\Delta p = -B \frac{A \Delta s}{A \Delta x} \approx -B \frac{\partial s}{\partial x}
\]

Taking a derivative of \( s(x, t) \) w.r.t. \( x \), we find:

\[
\Delta p = B k s_m \sin(kx - \omega t) = v^2 \rho k s_m \sin(kx - \omega t)
\]

We typically write \( v^2 \rho k s_m = \Delta p \).
Two fans are watching a baseball game from different positions. One fan is located directly behind home plate, 18.3 m from the batter. The other fan is located in the centerfield bleachers, 127 m from the batter. Both fans observe the batter strike the ball at the same time, but the fan behind home plate hears the sound first. What is the time difference between hearing the sound at the two locations?

(a) 0.316 s
(b) 0.368 s
(c) 0.053 s
(d) 0.189 s
(e) 0.632 s

(note: use 345 m/s as the speed of sound.)
Interference

When two “coherent” waves combine at a common location, they undergo interference.
**Interference**

*When two “coherent” waves combine at a common location, they undergo interference.*

If the waves arrive in phase, they add—out of phase, they subtract.

![Diagram of interference](image.png)
For two waves of the same wavelength passing through a common point, the result depends entirely on their phase difference $\phi$. 

$$\phi = \frac{\Delta L}{\lambda} \pi$$
Interference

For two waves of the same wavelength passing through a common point, the result depends entirely on their phase difference $\phi$.

The path length difference $\Delta L = L_2 - L_1$ determines the phase difference:

$$\phi = \frac{\Delta L}{\lambda} 2\pi \quad (3)$$
Interference

When $\phi$ is an integer multiple of $2\pi$, the waves combine constructively.

$$\phi = m(2\pi) \text{ or } \frac{\Delta L}{\lambda} = 0, 1, 2, \ldots$$

$$m \in (0, 1, 2, \ldots)$$
Interference

When $\phi$ is an integer multiple of $2\pi$, the waves combine constructively.

$$\phi = m(2\pi) \text{ or } \frac{\Delta L}{\lambda} = 0, 1, 2, ...$$

When $\phi$ is an odd multiple of $\pi$, the waves combine destructively.

$$\phi = (2m + 1)\pi \text{ or } \frac{\Delta L}{\lambda} = 0.5, 1.5, 2.5, ...$$

$m \in (0, 1, 2, ..)$
Interference

A radio station has two transmitting towers that transmit electromagnetic waves uniformly in all directions on the west end and east end of Main Street. The same signal is broadcast at the same time from both towers. As you drive ten miles east to west on Main Street, what would you hear as you listen to the radio station broadcast from these two towers?

(a) The signal gets stronger as you drive the first five miles, but then the signal decreases as you travel the final five miles.

(b) The signal is somewhat stronger than compared to a single tower, with no variation.

(c) The signal alternates between increasing strength and decreasing strength as you drive the ten miles.

(d) The signal is the same as only one tower since you switch from one tower to the next when you cross halfway.

(e) To answer this question, one must know the amplitude of the broadcast signal.
Traveling waves carry energy at a particular rate known as power $P$. When concentrated over a certain area $A$, we get intensity:

$$I = \frac{P}{A} \text{ W/m}^2$$  \hspace{1cm} (4)
Traveling waves carry energy at a particular rate known as power $P$. When concentrated over a certain area $A$, we get intensity:

$$I = \frac{P}{A} \text{ W/m}^2$$

This energy can be absorbed by an object (e.g., a microphone) or passed through an object (e.g., an open window).
We can expand this relationship using conservation of energy:

\[ I = \frac{P}{A} = \frac{1}{A} \frac{2dK}{dt} \]
We can expand this relationship using conservation of energy:

\[
I = \frac{P}{A} = \frac{1}{A} \frac{2dK}{dt} = \frac{2}{A} \left(0.5dm v_s^2\right) \frac{dx}{dt}
\]

\[
I_{avg} = \frac{1}{2} \rho v_s \omega^2
\]
We can expand this relationship using conservation of energy:

\[
I = \frac{P}{A} = \frac{1}{2} \frac{2dK}{dt} = \frac{2}{A} \frac{(0.5dm v_s^2)}{dt} = \frac{1}{A} \frac{[(\rho A dx)(-\omega s_m \sin(kx - \omega t))]}{dt}
\]
We can expand this relationship using conservation of energy:

\[
I = \frac{P}{A} = \frac{1}{A} \frac{2dK}{dt} = \frac{2}{A} \left(0.5dm v_s^2\right) \frac{dt}{dt} = \frac{1}{A} \left[\left(\rho A dx\right)\left(-\omega s_m \sin(kx - \omega t)\right)\right]^2 \frac{dx}{dt} = \frac{\rho \omega^2 s_m^2 \sin^2(kx - \omega t)}{dt}
\]
We can expand this relationship using conservation of energy:

\[
I = \frac{P}{A} = \frac{1}{A} \frac{2dK}{dt} = \frac{2}{A} \frac{(0.5dm v_s^2)}{dt} = \frac{1}{A} \left[ (\rho A dx)(-\omega s_m \sin(kx - \omega t))^2 \right] = \frac{dx}{dt} \rho \omega^2 s_m^2 \sin^2(kx - \omega t)
\]

\[
I_{avg} = \frac{1}{2} \rho v \omega^2 s_m^2.
\]
If a source emits sound isotropically (equal in all directions), then the intensity drops as:

\[ I = \frac{P_s}{4\pi r^2} \] (5)

This is due to the area of the sphere increasing with \( r \).
If a source emits sound isotropically (equal in all directions), then the intensity drops as:

$$I = \frac{P_s}{4\pi r^2}$$

(5)

This is due to the area of the sphere increasing with $r$. 
Intensity and Level

Sound level \( \beta \) is defined based on a logarithmic scale:

\[
\beta = (10 \text{ dB}) \log \frac{I}{I_0}.
\]  

(6)

\( I_0 \) is a standard reference set to \( 10^{-12} \text{ W/m}^2 \).
Sound level $\beta$ is defined based on a logarithmic scale:

$$\beta = (10 \text{ dB}) \log \frac{I}{I_0}. \quad (6)$$

$I_0$ is a standard reference set to $10^{-12}$ W/m$^2$. 

### Table 17-2 Some Sound Levels (dB)

<table>

Intensity and Level

Why logarithmic? The human ear can detect intensities in a range spanning 12 orders of magnitude!
Why logarithmic? The human ear can detect intensities in a range spanning 12 orders of magnitude!

A large change in intensity results in a small change in sound level.
Software is used to amplify a digital sound file on a computer by 20 dB. By what factor has the intensity of the sound been increased as compared to the original sound file?

(a) 2  
(b) 5  
(c) 10  
(d) 20  
(e) 100
A sound level meter is used measure the sound intensity level. A sound level meter is placed an equal distance in front of two speakers (assume no interference). A signal of constant power may be sent to each of the speakers independently or at the same time. When either speaker is turned on, the sound level meter reads 90.0 dB. What will the sound level meter read when both speakers are turned on at the same time?

(a) 90.0 dB
(b) 93.0 dB
(c) 96.0 dB
(d) 100.0 dB
(e) 180.0 dB
When sound waves oscillate in a pipe (or on a string), the geometry of the object determines the possible wavelengths.
When sound waves oscillate in a pipe (or on a string), the geometry of the object determines the possible wavelengths.

In terms of frequency \( f = v / \lambda \):

\[
f = \frac{nv}{2L}, \quad n = 1, 2, 3, \ldots \quad \text{Open at both ends.}
\]

\[
f = \frac{nv}{4L}, \quad n = 1, 3, 5, \ldots \quad \text{Open at one end.}
\]
Music and Beats

When two waves of slightly different frequency mix, we see/hear a pattern that oscillates at the beat frequency $f_{\text{beat}} = f_1 - f_2$. 

The beat frequency is always less than the other two frequencies.
Music and Beats

When two waves of slightly different frequency mix, we see/hear a pattern that oscillates at the beat frequency $f_{\text{beat}} = f_1 - f_2$.

The beat frequency is always less than the other two frequencies.
Given that the first three resonant frequencies of an organ pipe are 200, 600, and 1000 Hz, what can you conclude about the pipe?

(a) The pipe is open at both ends and has a length 0.95 m.
(b) The pipe is closed at one end and has a length 0.95 m.
(c) The pipe is closed at one end and has a length 0.475 m.
(d) The pipe is open at both ends and has a length 0.475 m.
(e) It is not possible to have a pipe with this combination of resonant frequencies.
Doppler Effect

When an object emits sound while moving, the observed sound depends on the velocity of the source and detector in the medium (e.g., air).

When the detector moves toward the source:

\[ f' = f \left( \frac{v + v_D}{v - v_S} \right) \]
When an object emits sound while moving, the observed sound depends on the velocity of the source and detector in the medium (e.g., air).

\[ f' = f \pm \frac{v}{v_D} \pm \frac{v}{v_S} \]
**Doppler Effect**

*When an object emits sound while moving, the observed sound depends on the velocity of the source and detector in the medium (e.g., air).*

\[ f' = f \frac{v \pm v_D}{v \mp v_S} \]  

(top sign: toward—bottom sign: away)
Doppler Effect

When a source is moving at a speed $v_s$ faster than the speed of sound $v$, the sound waves pile up producing a shock wave.

Copyright © 2014 John Wiley & Sons, Inc. All rights reserved.
Doppler Effect

When a source is moving at a speed $v_s$ faster than the speed of sound $v$, the sound waves pile up producing a shock wave.

\begin{equation}
\sin(\theta) = \frac{v}{v_s}
\end{equation}
Doppler Effect

When a source is moving at a speed $v_s$ faster than the speed of sound $v$, the sound waves pile up producing a shock wave.

The mach cone has a half-angle:

$$\sin(\theta) = \frac{v}{v_s}$$

(8)
A child is swinging back and forth with a constant period and amplitude. A stationary horn is emitting a constant tone of frequency $f$. At which position(s) will the child hear the lowest frequency for the sound from the whistle?

(a) at B when moving toward A
(b) at B when moving toward C
(c) at C when moving toward B
(d) at C when moving toward D
(e) at both A and D
