[Received on 5 July 2007; revised on 3 March 2008]

In this paper, we study a finite-volume method for the numerical solution of a model fourth-order partial differential equation defined on a smooth surface. The discretization is done via a surface mesh consisting of piecewise planar triangles and its dual surface polygonal tessellation. We provide an error estimate for the approximate solution under the $H^1$-norm on general regular meshes. Numerical experiments are carried out on various sample surfaces to verify the theoretical results. In addition, when the underlying mesh is constructed by the so-called constrained centroidal Voronoi meshes, we propose a numerically demonstrated superconvergent scheme to compute gradients more accurately.

Keywords: mixed finite-volume discretization; PDEs on surfaces; fourth-order equations; error estimates.

1. Introduction

In this paper, we consider the numerical solution of some fourth-order partial differential equations (PDEs) defined on arbitrary surfaces or 2D Riemannian manifolds. PDEs of order four and higher have appeared in the mathematical models of many application problems, e.g. those related to the surface diffusion, chemical coating, cell membrane deformation, biomedical imaging and computer graphics (Bertalmio et al., 2001; Bertozzi et al., 2007; Bloor & Wilson, 2000; Clarenz et al., 2000; Du et al., 2004; Feng & Klug, 2006; Greer et al., 2006; Grinspun et al., 2006; Myers et al., 2002; Stam, 2003; Toga, 1998). In fact, since the computation of surface curvatures is related to the second-order derivatives of the surface parameterization, the variation of curvature-dependent interfacial energies (such as the bending elasticity energy) leads naturally to equilibrium conditions that are in the form of PDEs of fourth order or higher.

Motivated by the wide range of applications, various discretization techniques for fourth-order PDEs on surfaces have been developed that include direct discretizations on surface meshes based on finite-element methods, discrete geometric calculus or discretizations via level set and phase-field techniques for implicitly defined surfaces (Bajaj & Xu, 2003; Bertalmio et al., 2001; Du et al., 2004; Dziuk & Elliot, 2007b; Feng & Klug, 2006; Greer et al., 2006; Grinspun et al., 2006; Huiskamp, 1991; Meyer et al., 2003; Ratz & Voigt, 2006; Smereka, 2003; Xu et al., 2006; Xu & Zhao, 2003). Meanwhile,

finite-volume methods have also been extensively studied for the numerical solution of PDEs due to their discrete conservation properties; see for instance, Bank & Rose (1987), Baranger et al. (1996), Cai et al. (1991), Chou et al. (1998), Chou & Li (2000), Coudière et al. (2001), Croisille (2000), Droniou & Eymard (2006), Du & Ju (2005), Ewing et al. (2000), Eymard et al. (2006), Gallouët et al. (2000), Lazarov et al. (1996), Li et al. (2000), Morton & Süli (1991), Nicolaides (1992) and Thomas & Trujillo (1999). Though many theoretical investigations have focused on finite-volume methods for first- and second-order PDEs, there is relatively little discussion on the analysis of finite-volume methods applied to higher-order PDEs (Li et al., 2000; Wang, 2004), especially for high-order PDEs defined on general surfaces. Due to the lack of a comprehensive theoretical study, there have often been concerns that direct discretizations of high-order PDEs based on surface triangulations may require tremendous computational effort for varying geometries and it is not clear how higher-order geometric characteristics such as the derivatives of curvatures are to be well represented on triangulated surfaces (Burger, 2006; Greer et al., 2006; Huiskamp, 1991). The study presented in this paper is aimed at filling in such a gap by considering a finite-volume method based on the primal–dual meshes for the numerical solution of some linear fourth-order elliptic equations defined on smooth surfaces.

For an open bounded \( C^{k,\alpha} \)-hypersurface \( S \) in \( \mathbb{R}^3 \) (Dziuk, 1988; Hebey, 2000) with \( k \in \mathbb{N} \cup \{0\} \) and \( 0 \leq \alpha < 1 \), it may be represented globally by some oriented distance function (level set function) \( d = d(x) \) defined in some open subset \( \Omega \) of \( \mathbb{R}^3 \) such that \( S = \{ x \in \Omega | d(x) = 0 \} \) with \( d \in C^{k,\alpha} \) and \( \nabla d \neq 0 \) in \( \Omega \). The unit outward normal \( \hat{n}(x) = (n_1(x), n_2(x), n_3(x)) \) to the surface \( S \) (with increasing \( d \)) at \( x \) is given by \( \hat{n}(x) = \nabla d(x) / |\nabla d(x)| \), where \( | \cdot | \) denotes the Euclidean norm and \( \nabla \) denotes the standard gradient operator in \( \mathbb{R}^3 \). Without loss of generality, we assume that \( |\nabla d| = 1 \) in \( \Omega \). Let \( \nabla_s = (\nabla_{s,1}, \nabla_{s,2}, \nabla_{s,3}) = \nabla - (\hat{n} \cdot \nabla)\hat{n} \) denote the tangential (surface) gradient operator and \( \Delta_s = \nabla_s \cdot \nabla_s \) be the so-called Laplace–Beltrami operator on \( S \).

In this paper, we consider the case that \( S \) has no boundary, i.e. \( \partial S = \emptyset \), to avoid technical complications in the presentation (for \( \partial S \neq \emptyset \), the analysis has no essential difference if suitable boundary conditions are chosen). As an illustration of more general settings, we focus on the numerical study of the following classical fourth-order elliptic problem defined on \( S \):

\[
\Delta_s (a(x) \Delta_s u(x)) + b(x) u(x) = f(x) \quad \forall x \in S.
\]  

(1.1)

We assume that the surface \( S \) can be discretized via a surface mesh consisting of piecewise planar triangles and its dual piecewise surface polygons. Assumptions on the coefficients \( a \) and \( b \) and the right-hand side \( f \) are specified later. The model equation (1.1) is much simpler than many high-order PDEs associated with various applications which may be nonlinear and whose solutions may be coupled with the way in which the surface \( S \) is defined or is evolving. It nevertheless provides a good starting point to illustrate the error contributions from the approximations of the surfaces and PDEs with high-order surface derivatives. By adopting a second-order splitting, we construct a finite-volume discretization of the above equation and provide an optimal order error estimate for the approximate solution under the \( H^1 \)-norm. In addition, we also propose a scheme to compute gradients, which is shown through numerical examples to display superconvergence when the underlying mesh is given by the so-called constrained centroidal Voronoi meshes. Such meshes and their practical constructions have been extensively studied in Du et al. (2003). Thus, our study here serves as a justification of the feasibility and optimality of finite-volume-based approximations of high-order PDEs defined on general surfaces. Numerical tests are also provided to validate the theoretical analysis and offer hints on the practical performance of the finite-volume schemes.

The paper is organized as follows: we first discuss the problem formulation in Section 2, then we discuss the mixed-finite-volume discretization in Section 3. The \( H^1 \)-error analysis is presented in
Section 4, and the surface mesh construction and gradient recovery are discussed in Section 5. Numerical examples and final conclusions are given in Sections 6 and 7.

2. Problem formulation

First, we use $L^p(S)$, $W^{m,p}(S)$ and $H^m(S) = W^{m,2}(S)$ to denote the standard Sobolev spaces on $S$. It is customary to assume that $k + \alpha \geq 1$ and $k + \alpha \geq m$ to make the space $H^m(S)$ well defined (Hebey, 2000). We further assume that $S$ is sufficiently smooth (say, of the class $C^4$) to avoid technical complications. In order to analyse the problem (1.1) rigorously, the following conditions on the regularity of the coefficients are always assumed.

**Assumption 2.1** The coefficients of (1.1) satisfy the conditions that $a \in W^{2,\infty}(S)$, $b \in W^{1,\infty}(S)$, with $a(x) \geq \alpha_1 > 0$, $b(x) \geq \alpha_2 > 0$ for $x \in S$ and $f \in L^2(S)$.

By introducing a new function $\nu = -a \Delta_s u$, the problem (1.1) then can be reduced to a problem represented by two second-order equations:

\[
\begin{align*}
-\Delta_s u(x) - \tilde{a}(x)\nu(x) &= 0, \\
-\Delta_s \nu(x) + b(x)u(x) &= f(x),
\end{align*}
\]

(2.1)

where $\tilde{a}(x) = 1/a(x)$ is also in $W^{2,\infty}(S)$. Such a reduction is naturally reminiscent of the reduction of a second-order equation to first-order systems which, in the finite-volume setting, leads to the methods studied by Chou et al. (1998), Croisille (2000), Droniou & Eymard (2006), Eymard et al. (2006) and Thomas & Trujillo (1999) and the references cited therein.

For any $u, \nu \in H^2(S)$, let us define the bilinear functional $A$ such that

\[ A(u, \nu) = \int_S \nabla_s u(x) \cdot \nabla_s \nu(x) ds. \]

We say that $(u, \nu) \in H^1(S) \times H^1(S)$ is a weak solution of (2.1) if and only if for any $\psi, \phi \in H^1(S)$,

\[
\begin{align*}
A(u, \psi) - (\tilde{a}\nu, \psi)_s &= 0, \\
A(\nu, \phi) + (bu, \phi)_s &= (f, \phi)_s,
\end{align*}
\]

(2.2)

where

\[ (w, \phi)_s = \int_S w(x)\phi(x) ds \]

for any $w \in L^2(S)$. First, we state some results on the well posedness in the following theorem.

**Theorem 2.2** Under Assumption 2.1, there exists a generic constant $c > 0$ such that for every $f \in L^2(S)$, there exists a unique solution $(u, \nu) \in H^2(S) \times H^2(S)$ for (2.1), and $(u, \nu)$ satisfies the following estimate:

\[ \|u\|_{H^2(S)} + \|\nu\|_{H^2(S)} \leq c \|f\|_{L^2(S)}. \]

(2.3)

The existence of a weak solution $u$ in $H^2(S)$ and its $H^2$-bound can be proved using the standard Lax–Milgram theorem and the Sobolev embedding results for spaces defined on a compact manifold (Hebey, 2000). The bound on $\nu$ can then be derived from regularity estimates for second-order elliptic equations, as those corresponding to (2.2), on the manifold $S$ (Aubin, 1982).
3. Mixed finite-volume discretization

We now present a mixed finite-volume discretization of (1.1). To make the notation simple, we now summarize some definitions that are used later. More precise definitions are to be found in the rest of the section.

3.1 Meshes and discrete spaces

Denote \( \mathcal{T} = \{T_i\}_{i=1}^m \) and \( \mathcal{T}^h = \{T_i^h\}_{i=1}^m \) to be the curved and planar triangulations of the surface \( S \) and its piecewise polygonal approximation \( S^h \), respectively. As defined later, these triangulations are related to each other by a lift map \( L \) from \( S^h \) to \( S \); \( \mathcal{K} \) and \( \mathcal{K}^h \) are the corresponding dual the tessellations of \( S \) and \( S^h \); \( \mathcal{U} \) and \( \mathcal{V} \) denote piecewise linear and piecewise constant function spaces defined on the triangulation \( S^h \) and the tessellation \( \mathcal{K}^h \), respectively; \( \Pi_u \) and \( \Pi_v \) are interpolation operators into \( \mathcal{U} \) and \( \mathcal{V} \), respectively, while \( \pi_u \) and \( \pi_v \) are the counterparts onto the pair of spaces induced by \( \mathcal{U} \) and \( \mathcal{V} \) on \( S \) through the lift \( L \); \( P_h \) and \( P \) are some projection operators and \( \mathcal{A} \), \( \mathcal{A}_G \) and \( \mathcal{A}_G \) denote some bilinear forms, with the subscript \( G \) symbolizing the use of Green’s formula in the definition.

For the smooth surface \( S \), we may assume that there is a strip (‘band’)

\[
U = \{x \in \Omega \mid \text{dist}(x, S) < \delta\}
\]

around \( S \) for some sufficiently small \( \delta > 0 \) such that there is a locally unique decomposition \( x = p(x) + d(x)\hat{n}(x) \) for any \( x \in U \), where \( p(x) \in S \), \( d(x) \) is the signed distance to \( S \) and \( \hat{n}(x) \) denotes the unit outward normal of \( S \) at \( p(x) \). The parameter \( \delta \) may be determined via the surface curvatures if \( S \) is sufficiently smooth. Then a function \( u \) defined on \( S \) can be extended uniquely in the strip by

\[
U(x) = u(p(x)) = u(x - d(x)\hat{n}(x)) \quad \forall x \in U.
\]

Let \( S \) be approximated by a sequence of continuous piecewise linear complex \( \{S^h \subset U\} \) which consists of a sequence of regular triangulations \( \{T^h = T^h_{i=1} \} \) with \( h \searrow 0 \) denoting the mesh parameter. In order to avoid global double covering, we further assume that for each point \( y \in S \) there is at most one point \( x \in S^h \) such that \( p(x) = y \), as suggested in Dziuk & Elliot (2007b). Each \( T^h \) contains vertices \( \{x_i\}_{i=1}^n \) on \( S \) (i.e. \( \{x_i\}_{i=1}^n \subset S \cap S^h \) ); see Fig. 1 (left). Clearly, \( S^h \) is globally of the class \( C^{0,1} \). We use \( m(\cdot) \) to denote the area for planar regions or the length for arcs and segments.

We assume that \( T^h \) satisfies the following mesh regularity condition:

\[
c_1 h^2 \leq m(T^h_i) \leq c_2 h^2,
\]

where \( h \) is the mesh parameter (size) for \( T^h \) and \( c_1 \) and \( c_2 \) are some positive constants independent of \( h \). By the uniqueness of the vector decomposition discussed above, we define \( T_i = \{p(x) \in S | x \in T^h_i \} \) and let \( \mathcal{T} = \{T_i\}_{i=1}^m \), then \( S = \bigcup_{i=1}^m T_i \).

Let \( \nabla_{S^h} = (\nabla_{S^h,1}, \nabla_{S^h,2}, \nabla_{S^h,3}) = \nabla - \hat{n}(\hat{n} \cdot \nabla) \) be the tangential gradient operator on \( S^h \), where \( \hat{n}(x) = (n_{h1}(x), n_{h2}(x), n_{h3}(x)) \) is the unit outward normal to \( S^h \). Since \( \hat{n} \) is constant on each planar triangle \( T^h_i \), \( \nabla_{S^h} \) needs only to be locally defined as a 2D gradient operator on the plane formed by \( T^h_i \) and the Sobolev space \( W^{m,p}(S^h) \) is well defined for \( m \leq 1 \).

We take a strategy similar to that adopted in Dziuk (1988) and Dziuk & Elliot (2007a) to solve the equation numerically on \( S^h \) instead of \( S \). We will directly discretize (2.1) (the mixed form) instead of the original problem (1.1) using a finite-volume method (Chou & Li, 2000; Li et al., 2000) (also called a finite-volume element method; see for instance, Cai et al., 1991; Ewing et al., 2000; Wu & Li, 2003).
To compare the discrete solution on $S^h$ with the continuous exact solution on $S$, we lift a function $U$ defined on $S^h$ to $S$ by

$$ L : U \rightarrow u = L(U), \quad \text{where} \quad u(y) = U(p^{-1}(y)) \quad \forall \ y \in S; $$

i.e. $U(x) = u(p(x)) = u(x - d(x)n(x))$ for $x \in S^h$.

Before discussing the discretization scheme, we first project the coefficients and the data $\tilde{a}, b$ and $f$ in (2.1) from $S$ onto $S^h$ by $\tilde{A} = L^{-1}(\tilde{a}), B = L^{-1}(b)$ and $F = L^{-1}(f)$. Since $S$ is sufficiently smooth, it is easy to find that $\tilde{A}, B \in W^{1, \infty}(T_i^h)$ and $F \in L^2(T_i^h)$ for any $T_i^h \in T^h$ and

$$ \|\tilde{A}\|_{W^{1, \infty}(T_i^h)} < c_1\|\tilde{a}\|_{W^{1, \infty}(S)}, \quad \|B\|_{W^{1, \infty}(T_i^h)} < c_2\|b\|_{W^{1, \infty}(S)} $$

for some positive constants $c_1, c_2 > 0$.

Let $U$ be the space of continuous piecewise linear polynomials on $S^h$ with respect to $T^h$:

$$ U = \left\{ U^h \in C^0(S^h) \mid U^h|_{T_i^h} \in \mathbb{P}_1(T_i^h) \right\}, $$

where $\mathbb{P}_k(D)$ denotes the space of polynomials of degree not larger than $k$ on any planar domain $D$. It is easy to see that $U \subset H^1(S^h)$ and for $U^h \in U$, we have $\nabla u^h$ constant on each triangle $T_i^h \in T^h$. A dual tessellation of $T^h$ on $S^h$ can be defined as seen in Fig. 1 (right). For each vertex $x_i$, let $\chi_i = \{i_s\}_{s=1}^{m_i}$ be the set of indices of its neighbours, $Q_{i,i+1}$ (where $i_s+1 = i_1$ if $s = m_i$) be the centroid of the triangle $\triangle x_ix_{i+1}$ and let $M_{i,j}$ be the midpoint of $\overline{x_ix_j}$ for $i \in \chi_i$. Let $K_i^T = \bigcup_{j \in \chi_i} Q_{i,i+j}$, where $Q_{i,i+j}$ denotes the polygonal region bounded by $x_i, M_{i,j}, Q_{i,i+j}$ and $M_{i,i+j}$ in general, $K_i^T$ is only piecewise planar and we define its projection on $S$ by $K_i = \{p(x) \in S \mid x \in K_i^T\}$. Let $\sigma$ denote the set of indices of all the vertices of $T^h$; then $K = \{K_i\}_{i \in \sigma}$ and $K_i^T = \{K_i^T\}_{i \in \sigma}$ may be viewed as dual tessellations of $S = \bigcup_{i=1}^m T_i$ and $S^h = \bigcup_{i=1}^m T_i^h$. In the remain of this paper, for simplicity, we will let $i_{j} = m_{j-1} + 1$ if $j > m_i$ when $i_j \in \chi_j$ ($x_{i_j}$ is a neighbour vertex of $x_i$); otherwise, $i_j$ will mean $i_{j-1} \mod (m_j + 1)$ if $j \geq 1$. Then $x_{i_j}$ is a vertex of $T_i^h = \triangle x_{i-1}x_{i+1}x_{i_j}$.
Denote by $\mathcal{V}$ the space of grid functions on $S^h$ with respect to $K^h$:
\[
\mathcal{V} = \left\{ f^h \mid f^h|_{K_i^h} \in \mathbb{P}_0(K_i^h) \right\}.
\]
A set of basis functions $\{ \psi^h_i \}_{i \in \sigma}$ of $\mathcal{V}$ is given by
\[
\psi^h_i(x) = \begin{cases} 
1, & x \in K_i^h, \\
0, & x \in S^h - K_i^h.
\end{cases}
\]

3.2 A discrete bilinear form and the finite-volume scheme

For any $\phi^h \in \mathcal{V}$ and $U \in H^1(S^h)$ with $U|_{T_i^h} \in H^2(T_i^h)$ for any $T_i^h \in T^h$, let us define the bilinear functional $A^h_G$ as
\[
A^h_G(U, \phi^h) = \sum_{i \in \sigma} \phi^h_i A^h_G(U, \psi^h_i),
\]
where $\phi^h_i = \phi^h(x_i)$ and
\[
A^h_G(U, \psi^h_i) = -\int_{\partial K_i^h} \nabla s \psi^h_i(x) \cdot \vec{n}_{K_i^h} \, ds_h
- \sum_{i,j \in \mathcal{E}_h} \int_{T_{i,j,i,j+1}} \nabla s \psi^h_i(x) \cdot \vec{n}_{K_i^h} \, ds_h
\]
with $\Gamma_{i,j,i,j+1} = \partial K_i^h \cap \triangle x_i x_j x_{i+1} = M_{i,j}Q_{i,j,i,j+1}M_{i,j+1}$ and $\vec{n}_{K_i^h}$ denoting the outward unit normal of $\partial K_i^h$. Then, the mixed finite-volume discretization for the fourth-order equation (1.1) is given as follows: find $(U^h, V^h) \in \mathcal{U} \times \mathcal{U}$ such that
\[
\begin{cases} 
A^h_G(U^h, \psi^h) - (AV^h, \psi^h)_{S^h} = 0 \\
A^h_G(V^h, \phi^h) + (BU^h, \phi^h)_{S^h} = (F, \phi^h)_{S^h}
\end{cases} \quad \forall \psi^h, \phi^h \in \mathcal{V},
\]
where
\[
(U, W)_{S^h} = \int_{S^h} U(x)W(x) \, ds_h
\]
for any $U$ and $W$ in $L^2(S^h)$.

3.3 A mass-lumping scheme

In the practical implementation, we first note that $U^h$ is piecewise linear on $S^h$ with respect to $T^h$ and $\nabla s_h U^h$ is constant on each triangle $\triangle x_i x_j x_{i+1}$. Defining
\[
\tilde{A}_i = \frac{1}{m(K_i^h)} \int_{K_i^h} \tilde{A}(x) \, ds_h, \quad B_i = \frac{1}{m(K_i^h)} \int_{K_i^h} B(x) \, ds_h, \quad F_i = \frac{1}{m(K_i^h)} \int_{K_i^h} F(x) \, ds_h
\]
as averages over $K_i^h$, we then use the following approximations:

$$
(\bar{A} V^h, \psi^h)_{sh} = \int_{S^h} \bar{A}(x)V^h(x)\psi^h(x)ds_h \approx \sum_{i \in \sigma} m(K_i^h)\bar{A}_i V_i^h \psi_i^h,
$$

$$(BU^h, \phi^h)_{sh} = \int_{S^h} B(x)U^h(x)\phi^h(x)ds_h \approx \sum_{i \in \sigma} m(K_i^h)B_i U_i^h \phi_i^h,$n

$$(F, \phi^h)_{sh} = \int_{S^h} F(x)\phi^h(x)ds_h \approx \sum_{i \in \sigma} m(K_i^h)F_i \phi_i^h,$n

where $V_i^h = V^h(x_i)$ and $U_i^h = U^h(x_i)$. Additionally,

$$\mathcal{A}_G^h(U^h, \psi^h) = \sum_{i \in \sigma} p_i \psi_i^h \mathcal{A}_G^h(U^h, \psi_i^h)$$

and with some careful calculations (Li et al., 2000), we can find that

$$\mathcal{A}_G^h(U^h, \psi_i^h) = -\sum_{i \in \chi_i} \left[q_i^1 (U^h_{i,j} - U^h_i) + q_i^2 (U^h_{i,j+1} - U^h_i) \right]$$

where $p_i = q_i^1 + q_i^2$ and

$$q_i^k = \frac{1}{8m(\Delta x_i x_j x_{i+1})} \left( (-1)^{k-1} |x_{i+1} - x_j|^2 + (-1)^k |x_i - x_{i+1}|^2 + |x_i - x_{i+1}|^2 \right), \quad k = 1, 2,$n

are constants depending only on the geometry of the surface triangulation $\mathcal{T}^h$.

With the numerical integration discussed above, we may transform (3.3) to the following linear system: for all $i \in \sigma$,

$$-\sum_{i,j \in \chi_i} p_{i,j} (U^h_{i,j} - U^h_i) - m(K_i^h)\bar{A}_i V_i^h = 0,$n

$$-\sum_{i \in \chi_i} p_{i,j} (V^h_{i,j} - V^h_i) + m(K_i^h)B_i U_i^h = m(K_i^h)F_i.$$n

Remark 3.1 In this paper, we only analyse the error of the finite-volume approximation (3.3). The above mass-lumped integration rule (3.4) turns out to be very effective in practical implementations, as demonstrated by our numerical experiments. The analysis given below can be generalized to (3.4), but as in Du & Ju (2005), more stringent regularity assumptions on the data and the exact solution would be required.
3.4 Some technical lemmas

Let us define some discrete inner products and norms associated with $T^h$ and a particular triangle $T^h_i = \Delta x_{i1} x_{i2} x_{i3} \in T^h$ as follows:

\[
(U^h, V^h)_{T^h_i} = \frac{1}{3} m(T^h_i) \left( \sum_{j=1}^{3} U^h(x_{ij}) V^h(x_{ij}) \right), \quad (U^h, V^h)_{T^h} = \sum_{T^h_i \in T^h} (U^h, V^h)_{T^h_i},
\]

\[
\|U^h\|_{0, T^h}^2 = (U^h, U^h)_{T^h_i}, \quad |U^h|_{1, T^h}^2 = m(T^h_i) \left| \nabla_s U^h \right|_{T^h_i}^2, \quad |U^h|_{1, T^h}^2 = \sum_{T^h_i \in T^h} |U^h|_{1, T^h_i}^2
\]

and $\|U^h\|_{0, T^h}^2 = (U^h, U^h)_{T^h}, \quad \|U^h\|_{1, T^h}^2 = \|U^h\|_{0, T^h}^2 + |U^h|_{1, T^h}^2$.

Thanks to the fact that $Q_{i1i2i3}$ is chosen to be the centroid of $\Delta x_{i1} x_{i2} x_{i3}$, we also have (Li et al., 2000)

\[
\|U^h\|_{0, T^h}^2 = (U^h, U^h)_{T^h} = \sum_{i \in \sigma} m(K^h_i) (U^h(x_i))^2.
\]

As the norms are defined locally on piecewise planar triangles, the following technical lemma is a trivial generalization of the same result given in Li et al. (2000).

**Lemma 3.2** There exist some generic constants $c_1, c_2 > 0$ such that for any $U^h \in \mathcal{U}$,

\[
c_1 \|U^h\|_{0, T^h} \leq \|U^h\|_{L^2(S^h)} \leq c_2 \|U^h\|_{0, T^h},
\]

\[
c_1 \|U^h\|_{1, T^h} \leq \|U^h\|_{H^1(S^h)} \leq c_2 \|U^h\|_{1, T^h}.
\]

For any $U \in C^0(S^h)$, denote by $\Pi_u(U)$ the interpolation of $U$ onto $\mathcal{U}$ and by $\Pi_v(U)$ the interpolation onto $\mathcal{V}$; i.e. $\Pi_u(U) \in \mathcal{U}$, $\Pi_v(U) \in \mathcal{V}$ and

\[
\Pi_u(U)(x_i) = U(x_i) = \Pi_v(U)(x_i)
\]

for all $i \in \sigma$. Then we have the following classic approximation results.

**Lemma 3.3** If $U \in H^2(T^h_i)$ for all $T^h_i \in T^h$, then there exist some generic constants $c_1, c_2 > 0$ such that for any $T^h_i \in T^h$,

\[
\|U - \Pi_u(U)\|_{L^2(T^h_i)} + h \|U - \Pi_u(U)\|_{H^1(T^h_i)} \leq c_1 h^2 \|U\|_{H^2(T^h_i)},
\]

\[
\|U - \Pi_u(U)\|_{L^2(T^h_i)} \leq c_2 h \|U\|_{H^1(T^h_i)}.
\]

The symmetry of the bilinear form $A^h_G(\cdot, \Pi_v(\cdot))$ in $\mathcal{U} \times \mathcal{U}$ can be verified as follows.

**Lemma 3.4** For any $U^h, V^h \in \mathcal{U}$,

\[
A^h_G(U^h, \Pi_v(V^h)) = \int_{S^h} \nabla_s U^h \cdot \nabla_s V^h \, ds_h = A^h_G(V^h, \Pi_v(U^h)).
\]
Proof. Let $T^h_i = \triangle x_{i_1} x_{i_2} x_{i_3}$; then we have
\[
\mathcal{A}_G(U^h, \Pi_v(V^h)) = \sum_{i \in \sigma} v^h_i \mathcal{A}_G(U^h, \Psi^h_i)
\]
\[
= -\sum_{i \in \sigma} \sum_{i_j \in X_i} v^h_i \int_{T_{i_{j_{j+1}}}^h} \nabla s_h U^h(x) \cdot \hat{n}_{K^h_i} \, d\gamma^h
\]
\[
= \sum_{T^h_i \in T^h} \left( -\sum_{j=1}^3 v^h_{i_j} \int_{\partial K^h_{i_j} \cap T^h_i} \nabla s_h U^h(x) \cdot \hat{n}_{K^h_{i_j}} \, d\gamma^h \right).
\]

Note that each $T^h_i$ can be regarded as a triangle in the $xy$-plane with some suitable affine mapping and $\nabla s_h$ as the standard 2D gradient operator. Then noticing that the result from Li et al. (2000, Theorem 3.2.1, p. 125) remains valid even though there are jumps in the normals between adjacent triangles, we may apply it to get
\[
\mathcal{A}_G(U^h, \Pi_v(V^h)) = \sum_{T^h_i \in T^h} m(T^h_i) \left( \nabla s_h U^h |_{T^h_i} \cdot \nabla s_h V^h |_{T^h_i} \right) = \int_{S^h} \nabla s_h U^h \cdot \nabla s_h V^h \, ds_h,
\]
which gives us the desired conclusion. \(\square\)

Note that the result of the above lemma is in fact a statement on the interesting connection between the finite-volume and the standard linear finite-element discretizations of the surface Laplace–Beltrami operator. From the proof of the lemma, we also see the following.

PROPOSITION 3.5 For any $U^h \in \mathcal{U}$,
\[
\mathcal{A}_G(U^h, \Pi_v(U^h)) = |U^h|^2_{H^1(S^h)}.
\]

The following lemma shows the equivalence of $\| \cdot \|^2_{L^2(S^h)}$ and $\langle \cdot, \Pi_v(\cdot) \rangle_{S^h}$ on $\mathcal{U}$.

LEMMA 3.6 Let $r(x)$ be a function defined on $S$ with $r \in W^{1,\infty}(S)$ and $r(x) > \alpha$ for some constant $\alpha > 0$. Let $R = L^{-1}(r)$. Then, there exist some generic constants $c_1, c_2 > 0$ such that
\[
c_1 \| U^h \|^2_{L^2(S^h)} \leq (RU^h, \Pi_v(U^h))_{S^h} \leq c_2 \| U^h \|^2_{L^2(S^h)}
\]
for any $U^h \in \mathcal{U}$ when $h$ is sufficiently small.

Proof. It has been shown in Li et al. (2000, Lemma 4.1.1, p. 191) that for any $T^h_i = \triangle x_{i_1} x_{i_2} x_{i_3} \in T^h$,
\[
(U^h, \Pi_v(U^h))_{T^h_i} = m(T^h_i) \left[ U^h_{i_1}, U^h_{i_2}, U^h_{i_3} \right] M \left[ U^h_{i_1}, U^h_{i_2}, U^h_{i_3} \right]^T
\]
with a positive definite matrix
\[
M = \frac{1}{108} \begin{bmatrix} 22 & 7 & 7 \\ 7 & 22 & 7 \\ 7 & 7 & 22 \end{bmatrix}
\]
Thus, there exist some generic constants \( c_1, c_2 > 0 \), independent of \( h \), such that

\[
c_3 \| U^h \|^2_{0, T_i^h} \leq (U^h, \Pi_0(U^h))_{T_i^h} \leq c_4 \| U^h \|^2_{0, T_i^h}.
\]

(3.5)

Let \( R_i = R(Q_{i_1 i_2 i_3}) \); then

\[
(RU^h, \Pi_0(U^h))_{S_h} = \sum_{T_i^h \in T^h} (RU^h, \Pi_0(U^h))_{T_i^h}
\]

\[
= \sum_{T_i^h \in T^h} R_i(U^h, \Pi_0(U^h))_{T_i^h} + \sum_{T_i^h \in T^h} ((R - R_i)U^h, \Pi_0(U^h))_{T_i^h}.
\]

With (3.5) and Lemma 3.2, we clearly have

\[
\sum_{T_i^h \in T^h} R_i(U^h, \Pi_0(U^h))_{T_i^h} \geq \alpha \sum_{T_i^h \in T^h} (U^h, \Pi_0(U^h))_{T_i^h} \geq c_5 \| U^h \|^2_{L^2(S^h)}
\]

(3.6)

and similarly we also have

\[
\sum_{T_i^h \in T^h} R_i(U^h, \Pi_0(U^h))_{T_i^h} \leq c_6 \| U^h \|^2_{L^2(S^h)}.
\]

(3.7)

Since \( R \in W^{1, \infty}(S^h) \), it is easy to find that

\[
\left| \sum_{T_i^h \in T^h} ((R - R_i)U^h, \Pi_0(U^h))_{T_i^h} \right| \leq \sum_{T_i^h \in T^h} \sum_{j=1}^{3} \left| U^h_{i_j} \right| \int_{T_i^h \cap \kappa^h_{i_j}} |(R - R_i)U^h| ds_h
\]

\[
\leq \sum_{T_i^h \in T^h} c_h \sum_{j=1}^{3} \left| U^h_{i_j} \right| \left[ m(T_i^h) \left( \left| U^h_{i_j} \right| + h \left| \nabla_{S_h} U^h|_{T_i^h} \right| \right) \right]
\]

\[
\leq \sum_{T_i^h \in T^h} c_h \sum_{j=1}^{3} \left[ \left| U^h_{i_j} \right|^2 + h \left| U^h_{i_j} \right| \left| \nabla_{S_h} U^h|_{T_i^h} \right| \right] m(T_i^h)
\]

\[
\leq c_h \| U^h \|^2_{L^2(S^h)} + c_h^2 \| U^h \|_{L^2(S^h)} \| U^h \|_{H^1(S^h)}
\]

\[
\leq c_h \| U^h \|^2_{L^2(S^h)},
\]

(3.8)

where the last step is obtained from the inverse inequality. The combination of (3.6–3.8) deduces that

\[
c_1 \| U^h \|^2_{L^2(S^h)} \leq (RU^h, \Pi_0(U^h))_{S_h} \leq c_2 \| U^h \|^2_{L^2(S^h)}
\]

when \( h \) is sufficiently small and the proof is complete.
3.5 Existence of the finite-volume solution

**Theorem 3.7** The discrete problem (3.3) possesses a unique solution when \( h \) is sufficiently small.

**Proof.** We need only to show that the following homogeneous system possesses solely the trivial solution:

\[
\mathcal{A}_G^h(U^h, \psi^h) - (\tilde{A}V^h, \psi^h)|_{\mathcal{S}_h} = 0
\]
\[
\mathcal{A}_G(V^h, \phi^h) + (BU^h, \phi^h)|_{\mathcal{S}_h} = 0 \quad \forall \psi^h, \phi^h \in \mathcal{V}.
\] (3.9)

In (3.9), let \( \psi^h = \Pi_h(V^h) \) and \( \phi^h = \Pi_h(U^h) \) and taking the difference of the two equations, we get

\[(\tilde{A}V^h, \Pi_h(V^h))|_{\mathcal{S}_h} + (BU^h, \Pi_h(U^h))|_{\mathcal{S}_h} = 0.
\]

By Lemma 3.6 with \( r(x) = \tilde{a}(x) \) and \( r(x) = b(x) \), respectively, and Assumption 2.1, we immediately get \( U^h = V^h = 0 \).

**Remark 3.8** If \( r, a \) and \( b \) are constant functions, then the requirement that \( h \) is sufficiently small can be removed from the conditions stated in Lemma 3.6 and Theorem 3.7.

4. The \( H^1 \)-error estimate

Let \( y = p(x) \) and set

\[\mu_h(x) = \frac{dS(x)}{ds_h(p(x))}, \quad \xi_h(x) = \frac{d\gamma(x)}{d\gamma_h(p(x))}.\]

Since \( S \) is sufficiently smooth, when \( h \) is small enough, it is easy to find

\[|d(x)| \leq c h^2 \quad \forall x \in S^h,\]

for some generic constant \( c \). Moreover, we have

\[|1 - \mu_h(x)| \leq c h^2, \quad |1 - \xi_h(x)| \leq c h^2, \quad |\tilde{u}(p(x)) - \tilde{u}_h(x)| \leq c h.\]

It is also easy to verify that

\[
\nabla_{s_h} U(x) = P_h \nabla U(x), \quad \nabla_s u(y) = P \nabla u(y), \quad \nabla U(x) = (P - dH) \nabla u(y),
\]

where \( H = (d_{s_i}, s_j) = (n_i, s_j) = (n_j, s_i), P_h = (\delta_{i,j} - n_{hi} n_{hj}) \) and \( P = (\delta_{i,j} - n_i n_j) \) are projections. Moreover, from Dziuk (1988), we have

\[PP = P, \quad PH = HP = H \quad \text{and} \quad \nabla_{s_h} U(x) = P_h(I - dH) \nabla_s u(y).\]

The following results are given in Dziuk (1988).

**Lemma 4.1** There exist some generic constants \( c_1, c_2, c_3, c_4, c_5 > 0 \) such that

\[c_1 \|U\|_{L^2(T^h_i)} \leq \|u\|_{L^2(T_i)} \leq c_2 \|U\|_{L^2(T^h_i)},\]
\[c_3 \|U\|_{H^1(T^h_i)} \leq \|u\|_{H^1(T_i)} \leq c_4 \|U\|_{H^1(T^h_i)},\]
\[|U|_{H^2(T^h_i)} \leq c_5 \left[ |u|_{H^2(T_i)} + h |u|_{H^1(T_i)} \right]\]

for any \( T_i \in \mathcal{T} \).
For any \( u \in C^0(S) \), we define the interpolants \( \pi_u(u) \) and \( \pi_v(u) \) by
\[
\pi_u(u) = \mathcal{L}(\Pi_u(L^{-1}(u))), \quad \pi_v(u) = \mathcal{L}(\Pi_v(L^{-1}(u))).
\]

Then we have the following results (see Dziuk, 1988; Hebey, 2000).

**Lemma 4.2** If \( u \in H^2(S) \), then there exist some generic constants \( c_1, c_2 > 0 \) such that
\[
\|u - \pi_u(u)\|_{L^2(S)} + h\|u - \pi_u(u)\|_{H^1(S)} \leq c_1 h^2\|u\|_{H^2(S)},
\]
\[
\|u - \pi_u(u)\|_{L^2(S)} \leq c_2 h\|u\|_{H^1(S)}.
\]

For any \( U^h \in \mathcal{U} \) and \( \Phi^h \in \mathcal{V} \), we lift them onto \( S \) by \( u^h = \mathcal{L}(U^h) \) and \( \phi^h = \mathcal{L}(\Phi^h) \), and let
\[
\psi_i^h(x) = \begin{cases} 1, & x \in K_i, \\ 0, & x \in S - K_i. \end{cases}
\]

Let \( \mathbf{n}_{K_i} \) denote the outward normal of \( \partial K_i \) on \( K_i \). For \( \phi^h \in \mathcal{V} \) and \( u \in H^1(S) \) with \( u|_{T_i} \in H^2(T_i) \) for any \( T_i \in \mathcal{T} \), we then define the bilinear functional \( A_G \) as
\[
A_G(u, \phi^h) = \sum_{i \in S} \phi_i^h A_G(u, \psi_i^h),
\]
where \( \phi_i^h = \phi^h(x_i) \) and
\[
A_G(u, \psi_i^h) = -\int_{\partial K_i} \nabla_s u(x) \cdot \mathbf{n}_{K_i} \, d\gamma.
\]

By Green’s theorem, we have
\[
A_G(u, \psi_i^h) = -\int_{K_i} \Delta_s u \, ds
\]
for any \( u \in H^2(S) \). Consequently, if \( (u, v) \in (H^2(S))^2 \) is the solution of the problem (2.1), then it holds that
\[
A_G(u, \psi^h) - (\tilde{a}v, \psi^h)_S = 0 \quad \forall \psi^h \in \mathcal{V},
\]
\[
A_G(v, \phi^h) + (bu, \phi^h)_S = (f, \phi^h)_S \quad \forall \phi^h \in \mathcal{V}.
\]

**Lemma 4.3** For any \( u \in H^2(S) \) and \( W^h \in \mathcal{U} \), there exists a generic constant \( c > 0 \) such that
\[
\left| A_G^h(U, \Pi_0(W^h)) - A_G^h(\Pi_u(U), \Pi_v(W^h)) \right| \leq ch\|u\|_{H^2(S)}\|W^h\|_{H^1(S)},
\]
\[
\left| (BU, \Pi_0(W^h))_S - (B\Pi_u(U), \Pi_v(W^h))_S \right| \leq ch\|u\|_{H^1(S)}\|W^h\|_{L^2(S)},
\]
\[
\left| (\tilde{A}U, \Pi_0(W^h))_S - (\tilde{A}\Pi_u(U), \Pi_v(W^h))_S \right| \leq ch\|u\|_{H^1(S)}\|W^h\|_{L^2(S)},
\]
where \( U = L^{-1}(u) \).
Proof. It is easy to see that $U \in H^2(T_i^h)$ for any $T_i^h \in \mathcal{T}^h$ and $W^h \in H^1(S^h)$ by Lemma 4.1. Let $W_i^h = W^h(x_i)$ and $T_i^h = \triangle x_i x_{i_2} x_{i_3}$ with $Q_i$ as the centroid of $T_i^h$; then we get

$$A^h_G(U, \Pi_v(W^h)) - A^h_G(\Pi_a(U), \Pi_v(W^h))$$

$$= A^h_G(U - \Pi_a(U), \Pi_v(W^h))$$

$$= \sum_{T_i^h \in \mathcal{T}^h} \left( \sum_{j=1}^{3} W_i^h - W_j^h \int_{K_{ij}^h \cap T_i^h} \nabla s_h(U - \Pi_a(U)) : \hat{n}_{K_{ij}^h} d\gamma_h \right)$$

$$= \sum_{T_i^h \in \mathcal{T}^h} \left( \sum_{j=1}^{3} (W_i^{h+2} - W_j^{h+1}) \int_{M_{ij+1,j}^h \cap Q_i} \nabla s_h(U - \Pi_a(U)) : \hat{n}_{K_{ij+1}^h} d\gamma_h \right).$$

In each triangle $T_i^h$, by the mesh regularity assumption, we have

$$|W_i^{h+2} - W_i^{h+1}| \leq h |\nabla s_h W^h|_{T_i^h} \leq c \|W^h\|_{1,T_i^h}.$$ 

Using the trace theorem on each $K_{ij}^h \cap T_i^h$ and the mesh regularity assumption again, we get

$$\int_{M_{ij+1,j}^h \cap Q_i} \nabla s_h(U - \Pi_a(U)) : \hat{n}_{K_{ij+1}^h} d\gamma_h$$

$$\leq ch^{1/2} \left( \int_{M_{ij+1,j}^h \cap Q_i} |\nabla s_h(U - \Pi_a(U))|^2 d\gamma_h \right)^{1/2}$$

$$\leq ch \left( h^{-1} |\nabla s_h(U - \Pi_a(U))|_{L^2(T_i^h)} + |\nabla s_h(U - \Pi_a(U))|_{H^1(T_i^h)} \right)$$

$$\leq ch \|U\|_{H^2(T_i^h)}.$$ 

By Lemmas 3.2 and 4.1 and the Cauchy–Schwarz inequality, we then obtain

$$|A^h_G(U, \Pi_v(W^h)) - A^h_G(\Pi_a(U), \Pi_v(W^h))| \leq \sum_{T_i^h \in \mathcal{T}^h} ch \|U\|_{H^2(T_i^h)} \|W^h\|_{1,T_i^h}$$

$$\leq ch \sum_{T_i^h \in \mathcal{T}^h} \|u\|_{H^2(T_i)} \|W^h\|_{1,T_i^h}$$

$$\leq ch \|u\|_{H^2(S)} \|W^h\|_{H^1(S^h)},$$

which gives us (4.3).

Also by Lemmas 3.3 and 4.1, we get

$$\left| (BU, \Pi_v(W^h))_{s_h} - (B\Pi_a(U), \Pi_v(W^h))_{s_h} \right|$$

$$= \sum_{i \in \sigma} \int_{K_i^h} B\Pi_v(W^h)(U - \Pi_a(U))ds_h$$
\[ \leq \|B\|_{L^\infty(S^h)} \int_{S^h} |\Pi_0(W^h)| |U - \Pi_u(U)| \, ds_h \]
\[ \leq c \|b\|_{L^\infty(S)} \|\Pi_0(W^h)\|_{L^2(S^h)} \|U - \Pi_u(U)\|_{L^2(S^h)} \]
\[ \leq c h \|u\|_{H^1(S)} \|W^h\|_{L^2(S^h)}, \]

which leads to (4.4).

Applying a similar analysis of (4.4) to \((\tilde{A} U, \Pi_0(W^h))_{S^h} - (\tilde{A} \Pi_0(U), \Pi_0(W^h))_{S^h}\), we get (4.5). This completes the proof. \(\square\)

**Lemma 4.4** For any \((u, v) \in (H^2(S))^2\) and \(W^h \in \mathcal{U}\), there exists a generic constant \(c > 0\) such that

\[ |A_G(u, \pi_0(w^h)) - A^h_G(U, \Pi_0(W^h))| \leq ch \|u\|_{H^2(S)} \|W^h\|_{H^1(S^h)}, \tag{4.6} \]
\[ |(bu, \pi_0(w^h))_S - (BU, \Pi_0(W^h))_{S^h}| \leq ch^2 \|u\|_{L^2(S)} \|W^h\|_{L^2(S^h)}, \tag{4.7} \]
\[ |(\tilde{u} u, \pi_0(w^h))_S - (\tilde{A} U, \Pi_0(W^h))_{S^h}| \leq ch^2 \|u\|_{L^2(S)} \|W^h\|_{L^2(S^h)}, \tag{4.8} \]
\[ |(f, \pi_0(w^h))_S - (F, \Pi_0(W^h))_{S^h}| \leq ch^2 \|f\|_{L^2(S)} \|W^h\|_{H^1(S^h)}, \tag{4.9} \]

where \(U = L^{-1}(u)\) and \(w^h = L(W^h)\).

**Proof.** It is easy to find that

\[ A_G(u, \pi_0(w^h)) - A^h_G(U, \Pi_0(W^h)) = I_1 + I_2, \]

where

\[ I_1 = \sum_{i \in \sigma} -W^h_i \left( \int_{\partial K_i} \nabla s u(x) \cdot \dot{n}_K_i(x) \, dy - \int_{\partial K^h_i} \nabla s_h U(x) \cdot \dot{n}_K_i(p(x)) \, dy_h \right), \]
\[ I_2 = \sum_{i \in \sigma} -W^h_i \left( \int_{\partial K^h_i} \nabla s_h U(x) \cdot (\dot{n}_K_i(p(x)) - \dot{n}_K^h_i(x)) \, dy_h \right). \]

For \(I_1\), we have

\[ I_1 = \sum_{i \in \sigma} -W^h_i \left( \int_{\partial K^h_i} \nabla s u(p(x)) \cdot \dot{n}_K_i(p(x)) \, dy_h - \int_{\partial K^h_i} \nabla s_h U(x) \cdot \dot{n}_K_i(p(x)) \, dy_h \right) \]
\[ = \sum_{i \in \sigma} -W^h_i \int_{\partial K^h_i} \left( \zeta_h \nabla s u(p(x)) - \nabla s_h U(x) \right) \cdot \dot{n}_K_i(p(x)) \, dy_h \]
\[ = \sum_{T_i \in \mathcal{T}} \left( -\sum_{j=1}^{3} W^h_{ij} \int_{\partial K^h_i \cap T^h_i} \left( \zeta_h \nabla s u(p(x)) - \nabla s_h U(x) \right) \cdot \dot{n}_K_i(p(x)) \, dy_h \right) \]
\[ = \sum_{T_i^h \in \mathcal{T}^h} \left( \sum_{j=1}^{3} \left( W^h_{ij+2} - W^h_{ij+1} \right) \int_{Q_i} \left( \zeta_h \nabla s u(p(x)) - \nabla s_h U(x) \right) \cdot \dot{n}_K^h_{ij+1} \, dy_h \right). \]
For $I_2$, we rewrite it as

$$I_2 = \sum_{T^h_i \in T^h} \left( \sum_{j=1}^{3} \left( W^h_{i,j+2} - W^h_{i,j+1} \right) \int_{M_{i,j+1,j+2}Q_i} \nabla s_h U \cdot \left( \tilde{n}_K_{i,j+1}(p(x)) - \tilde{n}_K^h_{i,j+1}(x) \right) \, dy_h \right).$$

Since $|\tilde{n}_K_i(p(x)) - \tilde{n}_K^h_i(x)| \leq ch$, by Lemmas 3.2 and 4.1 and the trace theorem, we see that

$$|I_2| \leq \sum_{T^h_i \in T^h} ch \| W^h \|_{1,T^h_i} \| U \|_{H^2(T^h_i)}$$

$$\leq ch \sum_{T^h_i \in T^h} \| u \|_{H^2(T_i)} \| W^h \|_{1,T^h_i}$$

$$\leq ch \| u \|_{H^2(S)} \| W^h \|_{H^1(S^h)}.$$  \hspace{1cm} (4.10)

We observe that

$$\tilde{\zeta}_h \nabla_s u(p(x)) - \nabla s_h U(x) = (\tilde{\zeta}_h I - P_h(I - dH)) P \nabla_s u(p(x))$$

$$= \tilde{\zeta}_h \left( P - \frac{1}{\tilde{\zeta}_h} P_h(I - dH) P \right) \nabla_s u(p(x)).$$

Since $|1 - \tilde{\zeta}_h| < ch^2$, we find for small $h$ that

$$\left| \tilde{\zeta}_h \left( P - \frac{1}{\tilde{\zeta}_h} P_h(I - dH) P \right) \right| \leq |P - P_h(I - dH) P| + ch^2$$

$$\leq |P - P_h P| + ch^2$$

$$\leq ch + ch^2$$

$$\leq ch.$$

So we know that

$$|\tilde{\zeta}_h \nabla_s u(p(x)) - \nabla s_h U(x)| \leq ch |\nabla_s u(p(x))| \leq ch |\nabla s_h U(x)|.$$

Then, using similar analysis as for $I_2$, we can show that

$$|I_1| \leq ch \| u \|_{H^2(S)} \| W^h \|_{H^1(S^h)}.$$  \hspace{1cm} (4.11)

Combining (4.11) with (4.10), we get the first estimate (4.6). Note that

$$\left| (bu, \pi_o(w^h))_S - (BU, \Pi_0(W^h))_{S^h} \right| = \int_S bu \pi_o(w^h) \, ds - \int_{S^h} BU \Pi_0(W^h) \, ds_h$$

$$= \int_{S^h} BU \Pi_0(W^h) \mu_h \, ds_h - \int_{S^h} BU \Pi_0(W^h) \, ds_h$$

$$= \int_{S^h} (1 - \mu_h) BU \Pi_0(W^h) \, ds_h$$

$$\leq ch^2 \| b \|_{L^\infty(S)} \| U \|_{L^2(S^h)} \| W^h \|_{L^2(S^h)}$$

$$\leq ch^2 \| u \|_{L^2(S)} \| W^h \|_{L^2(S^h)}.$$

we get the second estimate (4.7). Using a similar analysis to the above, we also can get (4.8).
Finally, we have
\[
| (f, \pi_v (w^h))_S - (F, \Pi_v (W^h))_{S_h} | = \left| \int_S f(x) \pi_v (w^h) (x) \, ds - \int_{S_h} F(x) \Pi_v (W^h) (x) \, ds_h \right|
\]
\[
= \left| \int_{S_h} (1 - \mu_h) F \Pi_v (W^h) \, ds_h \right|
\]
\[
\leq c h^2 \| F \|_{L^2(S^h)} \| W^h \|_{L^2(S^h)}
\]
\[
\leq c h^2 \| f \|_{L^2(S)} \| W^h \|_{L^2(S^h)}.
\]
This gives us (4.9).

**Lemma 4.5** Suppose that \((u, v) \in (H^2(S))^2\) is the solution of the problem (2.1), and \((U^h, V^h) \in \mathcal{U} \times \mathcal{U}\) is the solution of the discrete problem (3.3). Let \(U = L^{-1}(u)\) and \(V = L^{-1}(v)\); then there exists some generic constant \(c > 0\) such that
\[
\| U^h - \Pi_u (U) \|_{L^2(S^h)}^2 + \| V^h - \Pi_v (V) \|_{L^2(S^h)}^2
\]
\[
\leq c h \| f \|_{L^2(S)} [ \| U^h - \Pi_u (U) \|_{H^1(S^h)} + \| V^h - \Pi_v (V) \|_{H^1(S^h)} ].
\]  

**Proof.** For any \(W^h \in \mathcal{U}\), let \(w^h = L(W^h)\). By Lemmas 4.3 and 4.4, it holds that
\[
\| \mathcal{A}_G^h (\Pi_u (U), \Pi_v (W^h)) - \mathcal{A}_G (u, \pi_v (w^h)) \|
\]
\[
\leq \| \mathcal{A}_G^h (\Pi_u (U), \Pi_v (W^h)) - \mathcal{A}_G^h (\Pi_u (U), \Pi_v (W^h)) \|
\]
\[
+ \| \mathcal{A}_G^h (\Pi_u (U), \Pi_v (W^h)) - \mathcal{A}_G (u, \pi_v (w^h)) \|
\]
\[
\leq c h \| u \|_{H^2(S)} \| W^h \|_{H^1(S^h)}
\]  

and
\[
\left| (\Pi_u (\bar{A} V), \Pi_v (W^h))_{S_h} - (\bar{a} v, \pi_v (w^h))_S \right|
\]
\[
\leq \left| (\Pi_u (\bar{A} V), \Pi_v (W^h))_{S_h} - (\bar{A} V, \Pi_v (W^h))_{S_h} \right| + \left| (\bar{A} V, \Pi_v (W^h))_{S_h} - (\bar{a} v, \pi_v (w^h))_S \right|
\]
\[
\leq c h \| \bar{A} V \|_{H^1(S)} \| W^h \|_{L^2(S^h)} + c h \| \bar{a} v \|_{H^1(S)} \| W^h \|_{L^2(S^h)}
\]
\[
\leq c h \| v \|_{H^1(S)} \| W^h \|_{L^2(S^h)}
\]  

since \(\bar{a} \in W^{2, \infty}(S)\). Moreover,
\[
\left| (\Pi_u (\bar{A} V), \Pi_v (W^h))_{S_h} - (\bar{A} \Pi_u (V), \Pi_v (W^h))_{S_h} \right|
\]
\[
= \left| (\Pi_u (\bar{A} V), \Pi_v (W^h))_{S_h} - (\bar{A} V, \Pi_v (W^h))_{S_h} \right|
\]
\[
+ \left| (\bar{A} V, \Pi_v (W^h))_{S_h} - (\bar{A} \Pi_u (V), \Pi_v (W^h))_{S_h} \right|
\]
\[
\leq \| \bar{A} V - \Pi_u (\bar{A} V) \|_{L^2(S^h)} \| W^h \|_{L^2(S^h)} + c h \| v \|_{H^1(S)} \| W^h \|_{L^2(S^h)}
\]
\[
\leq c h \| v \|_{H^1(S)} \| W^h \|_{L^2(S^h)}.
\]  

(4.15)
The combination of (4.14) and (4.15) leads to
\[ \left| (\tilde{A} \Pi_u(V), \Pi_o(W^h))_{sh} - (\tilde{A}v, \pi_o(w^h))_s \right| \leq c h \|v\|_{H^1(S)} \|W^h\|_{L^2(S^h)}. \quad (4.16) \]

By (4.2), it is easy to find that \((u, v)\) satisfies
\[ A_G(u, \pi_o(w^h)) - (\tilde{A}v, \pi_o(w^h))_s = 0. \quad (4.17) \]

Putting (4.13) and (4.16) into (4.17), we get
\[ \left| A_G^h(\Pi_u(U), \Pi_o(W^h)) - (\tilde{A}\Pi_u(V), \Pi_o(W^h))_{sh} \right| \leq c h \|f\|_{L^2(S)} \|W^h\|_{H^1(S^h)}. \quad (4.18) \]

Using the estimate (2.3), we get
\[ \left| A_G^h(\Pi_u(U), \Pi_o(W^h)) - (\tilde{A}\Pi_u(V), \Pi_o(W^h))_{sh} \right| \leq c h \|f\|_{L^2(S)} \|W^h\|_{H^1(S^h)}. \quad (4.19) \]

At the same time, we note that
\[ A_G(v, \pi_o(w^h)) + (bu, \pi_o(w^h))_s = (f, \pi_o(w^h))_s \quad (4.20) \]
and
\[ A_G^h(V^h, \Pi_o(W^h)) + (BU^h, \Pi_o(W^h))_{sh} = (F, \Pi_o(W^h))_{sh}. \quad (4.21) \]

Using similar techniques as in the above and noticing the difference between \((f, \pi_o(w^h))_s\) and \((F, \Pi_o(W^h))_{sh}\) given in Lemma 4.4, we can easily get
\[ A_G^h(\Pi_u(V) - V^h, \Pi_o(W^h)) + (B(\Pi_u(U) - U^h), \Pi_o(W^h))_{sh} \leq c h \|f\|_{L^2(S)} \|W^h\|_{H^1(S^h)}. \quad (4.22) \]

Now, let us set \(W^h = V^h - \Pi_u(V)\) in (4.19) and \(W^h = \Pi_u(U) - U^h\) in (4.22) and add them together. By the symmetry of \(A_G^h(\cdot, \Pi_o(\cdot))\) shown in Lemma 3.4, after reordering, we obtain the left-hand side of the above sum as
\[
\text{LHS} = \left[ A_G^h(\Pi_u(U) - U^h, \Pi_o(V^h - \Pi_u(V))) + A_G^h(\Pi_u(V) - V^h, \Pi_o(\Pi_u(U) - U^h)) \right] \\
+ \left[ -A_G^h(\Pi_u(V) - V^h, \Pi_o(V^h - \Pi_u(V)))_{sh} + (B(\Pi_u(U) - U^h), \Pi_o(\Pi_u(U) - U^h))_{sh} \right] \\
= \left[ -A_G^h(\Pi_u(U) - U^h, \Pi_o(V^h - \Pi_u(V)))_{sh} + (B(\Pi_u(U) - U^h), \Pi_o(\Pi_u(U) - U^h))_{sh} \right] \\
+ \left[ A_G^h(\Pi_u(V) - V^h, \Pi_o(V^h - \Pi_u(V)))_{sh} + (B(\Pi_u(U) - U^h), \Pi_o(\Pi_u(U) - U^h))_{sh} \right] \\
= (\tilde{A}(V^h - \Pi_u(V)), \Pi_o(V^h - \Pi_u(V)))_{sh} + (B(\Pi_u(U) - U^h), \Pi_o(\Pi_u(U) - U^h))_{sh}. 
\]
Hence, by the inequalities (4.19) and (4.22), we get
\[
(A(V^h - \Pi_a(V)), \Pi_v(V^h - \Pi_a(V)))_{S_h} + (B(U^h - \Pi_a(U)), \Pi_v(U^h - \Pi_a(U)))_{S_h}
\leq c h \|u\|_{H^2(S)} + \|v\|_{H^2(S)}[\|U^h - \Pi_a(U)\|_{H^1(S^h)} + \|V^h - \Pi_a(V)\|_{H^1(S^h)}]
\leq c h \|f\|_{L^2(S)}[\|U^h - \Pi_a(U)\|_{H^1(S^h)} + \|V^h - \Pi_a(V)\|_{H^1(S^h)}].
\] (4.23)

Note that \(U^h - \Pi_a(U), V^h - \Pi_a(V) \in \mathcal{U}\), using Assumption 2.1 and Lemma 3.6, it is then easy to deduce (4.12) from (4.23) and the proof is thus completed. \(\Box\)

**Theorem 4.6** Suppose that \((u, v) \in (H^2(S))^2\) is the solution of the problem (2.1) and \((U^h, V^h) \in \mathcal{U} \times \mathcal{U}\) is the solution of the discrete problem (3.3). Let \(u^h = \mathcal{L}(U^h)\) and \(v^h = \mathcal{L}(V^h)\), then there exists some generic constant \(c > 0\) such that
\[
\|u - u^h\|_{H^1(S)} + \|v - v^h\|_{H^1(S)} \leq c h \|f\|_{L^2(S)}.
\] (4.24)

**Proof.** We extend \(u, v\) onto \(S^h\) by \(U = \mathcal{L}^{-1}(u)\) and \(V = \mathcal{L}^{-1}(v)\). By Proposition 3.5, we have
\[
|U^h - \Pi_a(U)|_{H^1(S^h)}^2 + |V^h - \Pi_a(V)|_{H^1(S^h)}^2 = A^h_G(U^h - \Pi_a(U), \Pi_a(U^h - \Pi_a(U))) + A^h_G(V^h - \Pi_a(V), \Pi_a(V^h - \Pi_a(V))).
\]

Setting \(W^h = \Pi_a(U) - U^h\) in (4.19) and \(W^h = \Pi_a(V) - V^h\) in (4.22), adding them up and putting back into the above equality, we then obtain that
\[
|U^h - \Pi_a(U)|_{H^1(S^h)}^2 + |V^h - \Pi_a(V)|_{H^1(S^h)}^2
\leq \left| (A(\Pi_a(V) - V^h), \Pi_v(\Pi_a(U) - U^h))_{S_h} \right| + \left( B(\Pi_a(U) - U^h), \Pi_v(\Pi_a(V) - V^h) \right)_{S_h}
\leq c h (\|u\|_{H^2(S)} + \|v\|_{H^2(S)})[\|U^h - \Pi_a(U)\|_{H^1(S^h)} + \|V^h - \Pi_a(V)\|_{H^1(S^h)}]
\leq c h \|f\|_{L^2(S)}[\|U^h - \Pi_a(U)\|_{H^1(S^h)} + \|V^h - \Pi_a(V)\|_{H^1(S^h)}].
\] (4.25)

where the last inequality is due to Lemma 4.5.

The sum of (4.25) and (4.12) gives us
\[
\|U^h - \Pi_a(U)\|_{H^1(S^h)}^2 + \|V^h - \Pi_a(V)\|_{H^1(S^h)}^2
\leq c h (\|u\|_{H^2(S)} + \|v\|_{H^2(S)})[\|U^h - \Pi_a(U)\|_{H^1(S^h)} + \|V^h - \Pi_a(V)\|_{H^1(S^h)}]
\]
and consequently, by using (2.3), we get
\[
\|U^h - \Pi_a(U)\|_{H^1(S^h)} + \|V^h - \Pi_a(V)\|_{H^1(S^h)} \leq c h (\|u\|_{H^2(S)} + \|v\|_{H^2(S)}) \leq c h \|f\|_{L^2(S)}.
\] (4.26)
In addition, by Lemmas 4.1 and 4.2, we have
\[ \|U - \Pi_h(U)\|_{H^1(S)} \leq c\|u - \pi_a(u)\|_{H^1(S)} \leq ch\|u\|_{H^2(S)}, \] (4.27)
\[ \|V - \Pi_h(V)\|_{H^1(S)} \leq c\|v - \pi_a(v)\|_{H^1(S)} \leq ch\|v\|_{H^2(S)}. \] (4.28)

Combining (4.26)–(4.28), we finally obtain
\[ \|u - u^h\|_{H^1(S)} + \|v - v^h\|_{H^1(S)} \leq c\left(\|U - U^h\|_{H^1(S)} + \|V - V^h\|_{H^1(S)}\right) \]
\[ \leq c\left(\|U^h - \Pi_h(U)\|_{H^1(S)} + \|U - \Pi_h(U)\|_{H^1(S)}\right) \]
\[ + \|V^h - \Pi_h(V)\|_{H^1(S)} + \|V - \Pi_h(V)\|_{H^1(S)}\right) \]
\[ \leq ch\|f\|_{L^2(S)}. \]

This completes the proof.

5. Quality surface meshes and gradient recovery

The design of a sequence of high-quality surface triangulations (satisfying mesh regularity requirement) with increasing levels of resolutions is a challenging research subject in its own right. To ensure the accurate finite-volume solution, we now discuss a possible approach for obtaining regular and smooth meshes. The meshes of the surface S to be used in our numerical experiments for the discretization of PDEs on surfaces are generated by the so-called constrained centroidal Voronoi Delaunay triangulation (CCVDT) algorithm (Du et al., 2003). We now give a brief description below.

Given a density function \( \rho(x) \) defined on S, for any region \( V \subset S \), we call \( x^c \) the ‘constrained mass centroid of V on S’ if
\[ x^c = \arg \min_{x \in V} F(x), \quad \text{where} \quad F(x) = \int_V \rho(y)\|y - x\|^2 ds(y). \] (5.1)

The existence of solutions of (5.1) can be easily obtained by using the continuity and compactness of \( F \); however, solutions may not be unique. In general, given a Voronoi tessellation \( \mathcal{V} = \{x_i, V_i\}_{i=1}^n \) of S, the generators \( \{x_i\}_{i=1}^n \) do not coincide with \( \{x^c_i\}_{i=1}^n \), where \( x^c_i \) denotes the constrained mass centroid of \( V_i \) for \( i = 1, \ldots, n \). We refer to a Voronoi tessellation of S as a ‘constrained centroidal Voronoi tessellation’ (CCVT) if and only if the points \( \{x_i\}_{i=1}^n \) which serve as the generators of the associated Voronoi tessellation \( \{V_i\}_{i=1}^n \) are also the constrained mass centroids of those regions (Du et al., 2003), i.e. if and only if we have that
\[ x_i = x^c_i \quad \text{for} \quad i = 1, \ldots, n. \]

The CCVT is a generalization of the standard centroidal Voronoi tessellation (Du et al., 1999) which is a concept with many applications including mesh generation and optimization. The dual tessellation of CCVT of S is then called an CCVDT. Constrained centroidal Voronoi meshes on surfaces in \( \mathbb{R}^3 \) have many good geometric properties, see Du et al. (2003) and Du & Wang (2005) for detailed studies as well as efficient algorithms for constructing CCVT/CCVDT meshes.

For a constant density function, the generators \( \{x_i\}_{i=1}^n \) are uniformly distributed in some sense; the \( V_i \)s are all almost of the same size and most of them are similar convex surface hexagons; the mesh size \( h \) is approximately proportional to \( 1/\sqrt{n} \). For a nonconstant density function, the generators \( \{x_i\}_{i=1}^n \) are still locally uniformly distributed and it is conjectured that, asymptotically, \( h_i/h_j \approx (\rho(x_j)/\rho(x_i))^{1/4} \).
This property of local quasi-uniformity of CCVDT meshes gives us an excellent chance to recover the approximation of \( \nabla_s u \) and \( \nabla_s v \) in high order based on the \( \nabla_{sh} U^h \) and \( \nabla_{sh} V^h \).

Let us take a simple averaging scheme similar to the one suggested in Du & Ju (2005). For any vertex \( x_i \), let \( D_i = \{ T^h_j \mid T^h_j \in T^h, x_i \in T^h_j \} \), then set

\[
DU(x_i) = \frac{1}{\text{Card}(D_i)} \left( \sum_{T^h_j \in D_i} \nabla_{sh} U|_{T^h_j} \right), \quad DV(x_i) = \frac{1}{\text{Card}(D_i)} \left( \sum_{T^h_j \in D_i} \nabla_{sh} V|_{T^h_j} \right).
\]

Now, let the vector-valued functions \( DU^h \) and \( DV^h \) be the corresponding piecewise-defined functions on \( S^h \) that interpolate \( \{ DU(x_i) \}_{i=1}^n \) and \( \{ DV(x_i) \}_{i=1}^n \), respectively. We also use \( Du^h = \mathcal{L}(DU^h) \) and \( Do^h = \mathcal{L}(DV^h) \) as the new approximations to the surface gradients \( \nabla_s u \) and \( \nabla_s v \), respectively. We expect that this averaging scheme with the underlying CCVDT mesh on \( S \) gives second-order approximations to \( \nabla_s u \) and \( \nabla_s v \) in \( L^2 \)-norm and first-order approximations in \( H^1 \)-norm. Then, the same averaging scheme can be applied to \( Du^h \) and \( Do^h \) to recover more accurately the tensors \( \nabla_s (\nabla_s u) \) and \( \nabla_s (\nabla_s v) \), respectively. A numerical demonstration of this superconvergent recovery is given in the later numerical experiments.

6. Numerical experiments

To illustrate the finite-volume method proposed and analysed in the paper and to validate the sharpness of the convergence rates (CRs) proved in the previous sections, numerical experiments are performed for some model geometries with some given exact solutions of (1.1). The simple mass-lumped scheme (3.4) is used in the practical implementation.

Let \( n_i \) denote the number of nodes of the mesh at the \( i \)th level and \( u^{h,i} \) the corresponding discrete solution, then we calculate the CR with respect to the norm \( \| \cdot \| \) by

\[
\text{CR} = \frac{2 \log(\|u - u^{h,i}\|/\|u - u^{h,i-1}\|)}{\log(n_{i-1}/n_i)}.
\]

**Example 6.1** The surface \( S \) is chosen to be the unit sphere \( S = \{ x \in \mathbb{R}^3 \mid x_1^2 + x_2^2 + x_3^2 = 1 \} \), and the outward normal at \( x \in S \) is given by \( \mathbf{n}(x) = x/\|x\| \). Let the coefficients in (1.1) be given by \( a(x) = 1 + 3x_1^2 \) and \( b(x) = 1 + x_3^2 \). The exact solution is chosen to be \( u(x) = 10x_1x_2x_3(x_1^2 - x_2^2) \) and consequently

\[
v(x) = -a(x)\Delta_x u(x) = 300x_1x_2x_3(x_1^2 - x_2^2)(1 + 3x_2^2)/(x_1^2 + x_2^2 + x_3^2).
\]

The right-hand side \( f(x) \) is set correspondingly from (1.1). We note that the norms of the exact solution are \( \|u\|_{L^2(S)} \approx 1.2024 \times 10^{100}, \|u\|_{H^1(S)} \approx 3.6698 \times 10^{101} \) and \( \|u\|_{L^2(S)} \approx 3.6698 \times 10^{101} \). Let \( h_{\max} \) denote the largest diameter of the surface mesh, then the corresponding \( h_{\max} \) for each mesh level is 0.5973, 0.3194, 0.1705, 0.0887 and 0.0457, respectively. The computational results are reported in Table 1. Some meshes and corresponding discrete

[Fig. 2. Discrete solution $u_h$ (top line) and $v_h$ (bottom line) for Example 6.1 with 104, 410 and 1634 nodes, respectively.]

Solutions are also plotted in Fig. 2, with the variations in colours representing the different values of the numerical solution. The CR is obviously consistent to our theoretical analysis and the errors for both $u$ and $v$ are about the same order when taking into account the difference in their respective norms. The gradient recovery scheme for the first-order derivatives is also seen to give an extra order of accuracy. For the second-order derivatives, the CR is expected to be at least linear, but the computation shows that the rate behaves nearly to be second order (see Table 2).

**Example 6.2** Now, we let the surface $S$ to be an ellipse defined by $S = \{x \in \mathbb{R}^3 | x_1^2 + x_2^2 + x_3^2/4 = 1\}$, and the outward normal at $x \in S$ is given by $\mathbf{n}(x) = \hat{r}/|\hat{r}|$ with $\hat{r} = (x_1, x_2, x_3/4)$. The coefficients in (1.1) are given by $a(x) = 1 + x_3^2$ and $b(x) = 1$. An exact solution is chosen to be $u(x) = e^{x_3^2-2}$ with the

The right-hand side $f(x)$ is again set correspondingly from (1.1). We note that the norms of the exact solution are $\| u \|_{L^2(S)} \approx 1.4988 \times 10^{+00}$, $\| u \|_{H^1(S)} \approx 6.9696 \times 10^{+00}$ and $\| u \|_{H^2(S)} \approx 3.6698 \times 10^{+01}$ and $\| v \|_{L^2(S)} \approx 8.3729 \times 10^{+01}$, $\| v \|_{H^1(S)} \approx 4.7398 \times 10^{+02}$ and $\| v \|_{H^2(S)} \approx 2.7276 \times 10^{+03}$, respectively.

Example 6.2 is also numerically solved by the finite-volume method studied here on five levels of CCVDT meshes with number of nodes $n_i = 147, 582, 2322, 9282$ and $37122$, respectively. We choose a nonuniform density $\rho(x) = e^{x^2/2} + 0.01$ for the CCVDT mesh construction in order to better capture the variations of $u$ on the surface. The constant 0.01 is used in $\rho$ to further regularize the resulting CCVDT mesh. The corresponding $h_{\max}$ for each mesh level is 0.8983, 0.5559, 0.2781,

**Fig. 3.** Discrete solution $u^h$ (top line) and $v^h$ (bottom line) for Example 6.2 with 147, 582 and 2322 nodes, respectively.
0.1464 and 0.0768, respectively. The computational results are reported in Tables 3 and 4. The meshes and corresponding discrete solutions are plotted in Fig. 3. The numerical accuracies of the solution, the recovered gradients and the recovered high-order derivatives are again consistent to those predicted by the analysis.

Although our analysis in the former sections is only for the case \( \partial S = \emptyset \), here we still use an example to test the performance of the proposed mixed finite-volume discretization for the case \( \partial S \neq \emptyset \).

**Example 6.3** We now consider a surface \( S \) given by \( S = \{ x \in \mathbb{R}^3 | (x_3 - x_2^2)^2 + x_1^2 + x_2^2 = 1, x_3 \geq x_2^2 \} \) (see Dziuk, 1988) with boundary

\[
\partial S = \{ (x_1, x_2, x_2 + \sqrt{1 - x_1^2 + x_2^2}) | x_1^2 + x_2^2 = 1 \}.
\]

The outward normal at \( x \in S \) is given by \( \overrightarrow{n}(x) = \frac{\vec{t}}{\| \vec{t} \|} \) with \( \vec{t} = (x_1, x_2(1 - 2(x_3 - x_2^2)), x_3 - x_2^2) \). We let \( a(x) = 1, b(x) = 1 \) in (1.1), and let \( f = f(x) \) be computed from (1.1) with an exact solution \( u \) given by \( u(x) = x_1x_2 \). We omit the long expression of \( v(x) = -\Delta_x u \) here. Dirichlet boundary conditions are used for both \( u \) and \( v \), i.e. both the values of \( u \) and \( v \) are specified on the boundary. We note that the norms of the exact solution are \( \| u \|_{L^2(S)} \approx 5.9370 \times 10^{-01}, \| u \|_{H^1(S)} \approx 1.6848 \times 10^{+00} \) and \( \| u \|_{H^2(S)} \approx 5.6461 \times 10^{+00} \) and \( \| v \|_{L^2(S)} \approx 5.0840 \times 10^{+00}, \| v \|_{H^1(S)} \approx 3.5017 \times 10^{+01} \) and \( \| v \|_{H^2(S)} \approx 6.2741 \times 10^{+02} \), respectively.

We solve Example 6.3 numerically on six levels of CCVDT meshes with number of nodes \( n_i = 64, 229, 865, 3361, 13429 \) and 52609, respectively. The uniform density function is used to generate the meshes. The corresponding \( h_{max} \) for each level mesh is 0.4597, 0.2719, 0.1482, 0.0834, 0.0469 and 0.0254, respectively. The computational results are reported in Tables 5 and 6. The meshes and corresponding discrete solutions are plotted in Fig. 4. Although the analysis given in the paper is limited to problems defined on compact surfaces without boundary, the example shows similar results for some boundary-value problems defined on a surface with boundary. The analysis for the latter case

**Fig. 4.** Discrete solution $u^h$ (top line) and $v^h$ (bottom line) for Example 6.3 with 64, 229 and 865 nodes, respectively.

is in fact very similar to the argument presented earlier for the compact surfaces. As for the gradient recovery scheme, the improvement in accuracy is not as dramatic as in the previous examples on the coarse meshes (the first few levels of CCVDT meshes); this is due to the fact that the coarse meshes lack sufficient resolution of the surface which experiences large curvature near the ends of the saddle so that it takes much larger number of nodes to obtain a well-approximated surface. In addition, the gradient recovery scheme is intended for interior nodes only, thus the boundary contributions degrade the performance in the whole domain. As the resolution level increases, the surface starts to enjoy much
better representation and the percentage of boundary nodes gets smaller so that the boundary effect also becomes less significant, we thus witness a significant improvement in the accuracy for both recovered first- and second-order derivatives. These results demonstrate that the finite-volume scheme can be used to accurately solve the high-order PDEs on surfaces which in turn can be useful to the development of algorithms for evaluating various surface differential operators and geometric features.

7. Conclusions

In this paper, we have studied a finite-volume method for a model fourth-order elliptic equation defined on a general smooth surface. Problems of the similar type often arise in various applications, and it is important to understand if the direct numerical discretizations such as the ones based on the finite-volume methods can yield accurate approximation especially when high-order differential operators on the surfaces are involved. Given a good approximation of the surface via planar triangulation and surface polygons, it is shown here that the $H^1$-error of the finite-volume solution based on the splitting of the fourth-order equation to second-order systems is of optimal order and thus provides accurate approximations to the solution of the PDEs. This gives a solid basis to the direct discretization approach for solving high-order PDEs on surfaces. Moreover, when an CCVT-based mesh is available (Du et al., 2003), they can provide highly accurate surface approximations. Based on such CCVDT meshes, a superconvergent gradient recovery can be efficiently and effectively constructed so that high-order derivatives of the numerical solutions can enjoy high resolution (although only numerically demonstrated), which in turn may be useful when additional geometry manipulation and information processing are needed in practical applications. We conclude by taking note that the present study serves as an initial exploration of the application of finite-volume methods to solve PDEs defined on general surfaces. The analysis is limited to a simple model equation, and it is given under the assumption that the surface can be discretized via a surface mesh consisting of piecewise planar triangles and its dual piecewise surface polygons. It will be an interesting issue to examine if it is possible to simplify the construction of the dual meshes and to relax the requirement on their approximation properties in practice. Connections of the finite-volume scheme with standard and other types of finite-element methods that are known for second-order equations in the Euclidean space (Bank & Rose, 1987; Croisille, 2000) may also be considered for high-order PDEs on surfaces. More challenging problems concerning the extensions to more complex nonlinear PDEs defined on deformable and possibly self-intersecting or singular surfaces also remain to be studied in the future, along with the study of problems where the definitions of the PDE and the underlying surface are coupled together so that they may evolve simultaneously. More computational benchmark studies are also desirable, especially in settings where the surfaces may undergo topological changes and are thus perhaps more appealing to an implicit representation, to make comparisons of the direct finite-volume discretization with other discretization methods.
