Introduction

Precision deflections measurements of an optical beam are useful in many fields of research. Using weak values [1], we have shown that these deflections can be amplified, which in turn improves the measurement sensitivity [2,3].

Due to photon shot noise, the signal to noise ratio (SNR) of a deflection measurement using a coherent light source scales as $\sqrt{N}$, where $N$ is the number of photons used in the process. Thus, it is typically desirable to increase the input power (or $N$) in order to improve the measurement sensitivity. One is often limited, however, by detector saturation.

Using this weak value method, we have found that (1) the SNR for such measurements approaches the standard quantum limit and (2) these measurements can be made using a detector with a low saturation intensity, regardless of the input beam power.

Experimental Setup

A linearly polarized coherent light source enters a Sagnac interferometer via a 50/50 beamsplitter (BS). The half-wave plate (HWP) and Soleil-Babinet compensator (SBC) adjust the interference between the two paths. The piezo driven mirror creates an opposite deflection for each path in the interferometer which is measured by the quadrant detector at the dark port. The mode quality of this port is monitored using a charge-coupled device (CCD) camera.

Theory (quantum treatment)

Initial Photon State: $|\psi_1\rangle = \left( e^{i\theta/2} |\uparrow\rangle + e^{-i\theta/2} |\downarrow\rangle \right)/\sqrt{2}$

Final Photon State: $|\psi_2\rangle = (|\uparrow\rangle + i|\downarrow\rangle)/\sqrt{2}$

Entangled state: $|\Psi\rangle = \int dx \psi(x)|x\rangle \exp(-iA_k x)$

where $A = |\uparrow\rangle \langle \uparrow| - |\downarrow\rangle \langle \downarrow|$

Post-selected state: $|\Psi_f\rangle = |\psi_f\rangle |\psi_i\rangle \int dx \psi(x)|x\rangle \exp(-iA_{w,k})$

where the weak value $A_w = \langle \psi_f | A | \psi_i \rangle / \langle \psi_f | \psi_i \rangle \approx -2i/\phi$

Post-selection probability: $P_{ps} = |\langle \psi_f | \psi_i \rangle|^2 = \sin^2(\phi/2)$

Measurement and SNR

Position measurement: $\langle x \rangle = k l_{md} / k_0$ amplified

amplification factor: $\alpha = 4k_0 \sigma^2 / \phi l_{md}$

SNR of measurement:

$\mathcal{R} = \sqrt{\frac{2}{\pi}} \frac{\sqrt{Nd}}{\sigma}$

amplified

$\mathcal{R}_A = \alpha \mathcal{R}$

Expression with noise:

$\langle x \rangle = \frac{1}{\mathcal{R} \mathcal{P}_\text{tot}} \left( \sigma \frac{S_R}{\sqrt{t}} \right)$

Results

Position measurement, amplified

Using weak value formalism we have predicted and have experimentally shown that the precision of a beam deflection measurement can be increased up to the standard quantum limit. We have demonstrated this improvement using a large beam radius and low light intensity on the quadrant detector.
